CN Assignment 11

Q1

In a real time message application implement a sliding window protocol to manage message delivery between client & ensure the way message are delivered in order and the no of message are lost.

=>

Sliding window protocol is a method used in network communication to ensure that data is delivered reliably in the correct order and without loss, it manages the flow of messages between a sender & a receiver by maintaining between a sender & a receiver a message can be sent before sending an acknowledgment.

1. Window size - The window represents a sequence of message frames that can be sent without waiting for acknowledgment. If window size is N , the sender can send upto N message at a time.
2. Message sequence number - Each message is assigned a sequence number. This number helps the receiver identify the order of message & detect any missing message.
3. Acknowledgment - After receiving a message the receiver sends an acknowledgment back to the sender indicating message has been received.
4. Retransmission: - If an acknowledgment is not received for a message within a certain period the sender will retransmit the message.

5. Flow control - The sliding window also handles flow control, ensuring that sender does not overwhelm receiver with too many messages.

Working of sliding window Protocol in Real time messaging.

Sender Side :-

- Sender maintains a window of N , it can send N messages without waiting for an acknowledgement.
- Each message is tagged with a sequence number.
- After sending each message the sender starts a timer for each message the sender starts a wait.
- If the timer expires without receiving an acknowledgement the sender retransmits the message.

Receiver Side

- The receiver checks the sequence number of each incoming message.
- If the message are in order, the receiver sends an acknowledgement.
- If a message is out of order, it may either suffer the message & wait for the missing message, or request a retransmission from the sender.

Q2

Below is a hexadecimal dump of a UDP datagram captured.

```
e2 a7 00 00 00 20 74 9e 0e ff 00 00 00 01 00 01
00 00 00 00 06 69 73 81 79 61 70 00 00 01 00 01
```

- What is source port number?
- What is destination port number?
- What is total length of user datagram?
- What is total length of data?
- Is packet directed from client to server or vice versa?

=>

Following is the UDP data gram structure

- Source port number = $(F2A1)_{16}$
- Destination port number = $(0000)_{16}$
- Total length of the user datagram
 $= (0000)_{16} = (32)_{10} \text{ bytes}$
- Total length of data = Total length - header length
 $= 32 - 8$
 $= 24 \text{ bytes}$

8 bytes

UDP datagram

11 byte

16 byte

32 bits
